Executive Summary

The purpose of this study is to analyze and review the existing hydrology of Phases 1 and 2 of the Taclor Solar Project (Project or Site) and any impacts that the hydrology may play in the design of the proposed solar array. This report was prepared to be used by the Project Team in the design and layout of the Project and not intended for submittal to reviewing agencies for stormwater permitting.

The Project Site is proposed on approximately 17 square miles and is located within Weld and Morgan Counties, Colorado, approximately 2.75 miles southwest of the city of Wiggins in Morgan County, Colorado. The Site is located on rough and varying land that generally slopes inwards towards the onsite reaches. The modeled watershed area encompasses approximately 94 square miles and generally drains northeast.

The analysis of the 100-year, 24-hour storm shows low water depths and velocities (Exhibits 7 through 8A) across the majority of the Site, outside of the onsite reaches and creeks. Higher flood depths and velocities exist within these creeks and their surrounding area. The floodplains onsite are fairly large; however, the flooding is generally well-contained within the floodplain limits. There are also scattered low-lying areas with localized ponding across the Project Site. Minimal velocities and scour are expected on site, outside of the onsite reaches and floodplains, due to the rough terrain and lack of consistent steep slopes.

The analysis of the 50-year, 24-hour storm event yielded similar results to those of the 100-year, 24-hour storm, but with slightly less severe depths, velocities, and scour (Exhibits 10-12).

Based on experience with similar projects, the majority of the Site is suitable for the planned development; however there are portions of the site which will be unusable for solar development, based on the presences of hazardous flows and velocities.

Planar Units Feet (U.S. Survey)

3.0 Existing Conditions

3.1 Project Location

The Project Site, Phases 1 and 2 of the Taelor Solar Project, covers approximately 17 square miles and is located within Weld and Morgan Counties, Colorado (Exhibit 1). The Project Site is located approximately 50 miles northeast of Denver, with the nearest town being Wiggins in Morgan County, Colorado. Wiggins is located 2.75 miles northeast of the Project Area (Exhibit 1).

3.2 Watershed Hydrology

The modeled watershed area encompasses approximately 94 square miles that generally discharges to the northeast. The watershed is primarily defined by Kiowa Creek, which originates south of the Project, entering the Project through its southwest corner and flowing northeast through its limits. Kiowa Creek is defined by a fairly wide floodplain, which can range from 2,000 ft to over a mile in width.

Jack Rabbit Creek flows into Kiowa Creek just within the southwest limits of the Site, also originating from the south, but just west of Kiowa Creek.

Rock Creek enters the watershed from the south, approximately 5 miles east of Kiowa Creek, and then flows north through the eastern portion of the Site. Rock Creek then flows into Kiowa Creek within the northeastern corner of the Project.

An additional unnamed tributary of Kiowa Creek enters the watershed from the southeast. The tributary flows north-northwest just east of the project, before flowing into Kiowa Creek roughly 2,500 ft downstream of its junction with Rock Creek, just off the eastern limits of the Site.

See Exhibits 2 and 3 for geospatial displays of the watershed and its features.

3.3 Onsite Conditions

The Project is located on varying landscape, defined by several reaches as well as distributed patches of rougher terrain. The northwestern portion of the site generally is rougher, containing rolling slopes of 1% to 4%, with rougher distributions of a sort of prairie-pothole landscape, defined by many pockets of low-lying depressions. This area minimally discharges; however, there is a subtle drainage pattern towards Kiowa Creek to the southeast.

The majority of the stretch of land extended from the southwestern corner to the northeastern corner of the Site is defined by the channel and floodplain of Kiowa Creek. The floodplain is generally flatter, with more consistent slopes generally less than 0.5%. The southeastern banks are generally made up of rolling terrain with slopes generally between 1% to 4%, whereas the northwestern banks are more comprised of the rough, prairie-pothole landscape. Kiowa Creek discharges offsite to the northeast.

The eastern portion of the project is generally covered by the channel and floodplain of Rock Creek, as it flows north and merges with Kiowa Creek. The banks are generally made up of the rolling landscape; however, there are small instances of isolated rough prairie-pothole patches. The majority of the runoff from this portion of the site discharges offsite to the northeast via Kiowa Creek.

US Fish and Wildlife Service National Wetlands Inventory (NWI Wetlands) provides information on the distribution of US wetlands and are shown in Exhibit 3. The NWI Wetlands dataset is not all-inclusive and other wetlands not shown may exist. The landcover on the Project area is primarily pastureland and agricultural row crops (Exhibit 6) and has soils that are primarily belonging to Hydrologic Soil Group (HSG) A (Exhibit 5). Typically, A soils are sands.

The main potential hydrologic issues on Site are riverine flooding and erosive velocities, although isolated pockets of ponding should also be considered.

3.4 FEMA Flood Zones

FEMA has completed a study to determine flood hazards for the selected location; the project area is covered by FIRM panels 08087C0575D, 08123C2035E, 08123C2050E, and 08087C0555D (Appendix C). FIRM panels 08123C2035E and 08123C2050E are within Weld County and have not yet been printed; however, electronic flood zones have been delineated for portions of these panels. The Project contains areas of FEMA Zone A flood hazards (Exhibits 3, 7, and 10), particularly associated with Rock Creek and the portions of Kiowa Creek within Morgan County, A FEMA Zone A flood hazard is a 100-year flood hazard with no defined base flood elevation. Preliminary FIRM panels have been issued for Weld County; however, they have not yet been made available or effective.

4.0 Proposed Conditions

4.1 Proposed Conditions

The majority of the proposed solar facility will consist of above ground mounted solar modules. A climate-specific grass seed mix should be planted below the modules and would make up a majority of the land cover. A small amount of impervious surface will be added from the gravel access roads and electrical equipment pads. The Project should be designed to minimize grading and maintain existing drainage patterns. A flood analysis of pre-development and post development depths may need to be completed once civil design is finalized for permitting purposes.

4.2 Post-Construction Stormwater Management

A desktop review of Weld County and Morgan County Stormwater Management and Drainage Requirements identified the 2020 Weld County Engineering and Construction Criteria manual, the Morgan County Zoning Regulations, and the Mile High Flood District (MHFD) Criteria Manual. As the Site design progresses, these manuals and documents should be referenced in order to assure that the Site design complies with any rate control, volume control, or water quality requirements that are outlined within them.

The typical solar project's low-impact development technique of converting the land cover from a row crop field to a meadow grass will provide post-construction stormwater management to meet most agency requirements. The proposed meadow grass will act as a vegetated filter providing both runoff treatment and reduction when compared to existing conditions. As the Project design advances, the post-construction stormwater management should be reviewed in further detail with the County Engineer.

5.0 FLO-2D Modeling

5.1 FLO-2D Modeling Overview

FLO-2D is a physical process model that routes rainfall runoff and flood hydrographs over flow surfaces or in channels using the dynamic wave approximation to the momentum equation. FLO-2D offers advantages over 1-D models and unit hydrograph methods by allowing for breakout flows and visualization of flows across a potential site. The primary inputs are a DTM (elevation data), curve numbers, and precipitation. No culverts were included in the model; all roadways and berms were assumed to overtop.

A FLO-2D model with 50-foot grid cells was utilized to model the watershed within and directly impacting the Project Site.

5.2 Elevation Data

The elevation data input into the FLO-2D model was 2ft LiDAR data from The National Map (Exhibit 6). This data was exported as a single digital terrain model (DTM), which is read directly into FLO-2D.

5.3 Watershed Soils and Land Cover

USDA-NRCS SSURGO soil data provides soil types within the Project boundary and full coverage of the contributing watershed. Soils are primarily classified as Hydrologic Soil Group (HSG) A within the Project boundary (Exhibit 4). Land cover was obtained from the USDA 2013 Crop Data Layer. Exhibit 5 displays the land cover classes for the entire watershed. Curve numbers were applied to each

grid cell in the FLO-2D model based on intersecting the grid with the curve numbers (Exhibit 6).

5.4 Precipitation

Precipitation data was downloaded from NOAA Atlas 14 (Appendix A) and used for the FLO-2D analysis for the 100-Year and 50-Year, 24-Hour storm events. Using the 100-Year and 50-Year rainfall depths of 4.54 inches and 3.95 inches. respectively, for this location allows for the best initial analysis in order to determine the worst areas of flooding and erosion during multiple different storm events. Rainfall inputs were distributed based on a site-specific nested Atlas 14 distribution pattern.

5.5 Inflows

Jack Rabbit Creek, Kiowa Creek, Rock Creek, and an Unnamed Tributary of Kiowa Creek all flow into the modeled watershed. USGS StreamStats provides 50-year and 100-year peak flow rates for these reaches (Appendix D). In order to account for these flows, inflow hydrographs were created at each location where these reaches enter the modeled watershed. Table 3 below displays the flow rates for each reach and flood event. See Exhibits 7 and 10 for inflow locations.

Table 3 - Inflow Rates

Decel	50-Year Peak	100-Year Peak
Reach	Flow (cfs) Flow (cfs 3,250 4,66 28,900 40,70 8,780 12,50	Flow (cfs)
Jack Rabbit Creek	3,250	4,660
Kiowa Creek	28,900	40,700
Rock Creek	8,780	12,500
Unnamed Tributary	2,750	3,940

6.0 Flood Analysis Results

6.1 Existing Conditions Flood Analysis

The 100-year, 24-hour analysis shows low to moderate water depths and low velocities (Exhibits 7 through 8A) across the majority of the Site, outside of the influence of the onsite reaches. During a 100-year storm, the flood depths across the majority of the Project Area are less than 0.5 feet with velocities less than 1 foot/second, with the exception of the flows within the main onsite creeks and their associated floodplains. The 100-year flood depths within the onsite portions of the main channels of Kiowa Creek and Rock Creek can easily exceed 10ft, whereas the depths within the floodplains are generally between 2ft to 8ft. The area where the two creeks converge results in a large area of more significant flooding, due to the convergence of the creeks' floodplains. Although the extents of the floodplains are fairly wide, the flooding within them is generally well-contained to the floodplain

limits. The 100-year peak velocities within the channels can exceed 13 ft/second, whereas the velocities within the floodplain are generally between 1 ft/second and 6 ft/second. The majority of flood depths and velocities associated with the unnamed tributary to the east do not directly encroach onto the Project Area itself.

In addition to the riverine flooding, there are additional areas of isolated flooding within the more prairie-pothole portions of the site, particularly to the northwest. The 100-year flood depths within these pothole areas are generally less than 5ft, but have minimal velocities due to their disconnected nature. The presence of HSG A soils within the Project will likely help these flood depths infiltrate more quickly. See Table 3 below for a breakdown of 100-year flood depths within the Project Site.

Table 4 - Flood Depths Onsite

Peak Flow Depth (ft)	Percentage of Project Area Covered by Peak Flow Depths
0.00 - 0.49	56.5%
0.50 - 1.00	4.5%
1.01 - 1.50	5.6%
1.51 - 2.00	6.4%
2.01 - 2.50	5.9%
2.51 - 3.00	4.6%
3.01 - 4.00	5.9%
4.01 - 6.00	6.6%
6.01+	4.0%

See Exhibits 7 through 8A for areas within the Project with higher flood depths and velocities during the 100-year, 24-hour storm.

Overall, the results of the 50-year, 24-hour storm model were similar to those of the 100-year, 24-hour storm, but with slightly lower extremes. The exceedance of 13 ft flood depths within the creek channels is less common during the 50-year storm, although it still occurs in some areas. The majority of channel depths are generally less than 10 ft. Similarly, the presence of floodplain depths in excess of 7ft is less common during the 50-year storm, with the majority of the floodplain depths being less than 5ft. Within the isolated ponding locations, flood depths rarely exceed 4ft. Channel velocities are generally less than 10 ft/second, with floodplain velocities generally between 1 ft/second and 5.5 ft/second. See Exhibits 7 through 8A for areas within the Project with higher flood depths and velocities during the 50-year, 24-hour storm.

6.2 Scour

Minimal scour is expected onsite, outside of the main reaches and their associated floodplains, during both the 50-year and 100-year storms (Exhibits 9 and 12). The scour depths calculated for this Project are based on HEC-18 Pier Scour Equations of a 6-inch-wide pile perpendicular to flow. Scour calculations consist of local scour only with unarmored soils and pile bases to provide the conservative local scour results. These scour results do not account for general, rill, or gully scour.

7.0 Recommendations

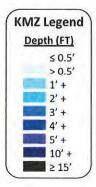

Based on experience on similar projects, the majority of the Site is suitable for the planned development; however, portions of the site, as is seen in Table 4 as well as Exhibits 7-12, will be unsuitable for solar development, due to the presence of hazardous flows and velocities. These areas should be reviewed and considered as Site design progresses, for areas of avoidance, as well as any potential locations where infrastructure could be designed to accommodate higher flood depths. Additionally, local stormwater requirements and regulations should be reviewed as the design progresses, in order to ensure Site compliance.

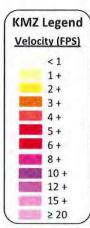

8.0 Next Steps

- 1. Final engineering design should account for the flood depths and velocities presented in Exhibits 7-11A.
- 2. Facilities to be elevated 1' above the 100-year, 24-hour peak flood elevations.
- 3. Proposed facilities should avoid FEMA Flood Zones located onsite.
- 4. Stormwater management should be revisited to ensure the final design meets the local and state requirements.

Precipitation frequency (PF) estimates in this table are based on frequency analysis of partial duration series (PDS).

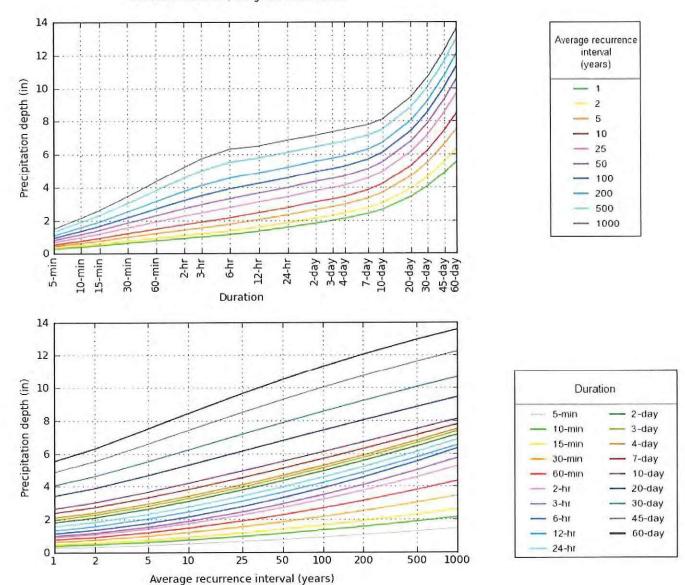

Numbers in parenthesis are PF estimates at lower and upper bounds of the 90% confidence interval. The probability that precipitation frequency estimates (for a given duration and average recurrence interval) will be greater than the upper bound (or less than the lower bound) is 5%. Estimates at upper bounds are not checked against probable maximum precipitation (PMP) estimates and may be higher than currently valid PMP values.

Please refer to NOAA Atlas 14 document for more information.
